

# Web Dev Basics 2

## CS571: Building User Interfaces

**Cole Nelson & Yaxin Hu**

# Before Lecture

- Clone [today's code](#) to your machine.
- Download and install [Postman](#)!

# Web Dev Basics 1

- The Web is made up of HTML, CSS, and JS!
  - **HTML:** structure
  - **CSS:** styling
  - **JS:** behavior
- CSS and JS can be applied to HTML inline, internal, or externally.

# Inline JavaScript

The JavaScript is included inside of the HTML element.

index.html

```
<html>
  <h1>Welcome to my webpage!</h1>
  <button onclick="console.log('hello world!')">Click Me!</button>
</html>
```

# Internal JavaScript

The JavaScript is included inside of the HTML.

index.html

```
<html>  
  <h1>Welcome to my webpage!</h1>  
  <script>  
    console.log("hello world!");  
  </script>  
</html>
```

# External JavaScript

The JavaScript is included from outside of the HTML.

index.html

```
<html>  
  <h1>Welcome to my webpage!</h1>  
  <script src='app.js'></script>  
</html>
```

app.js

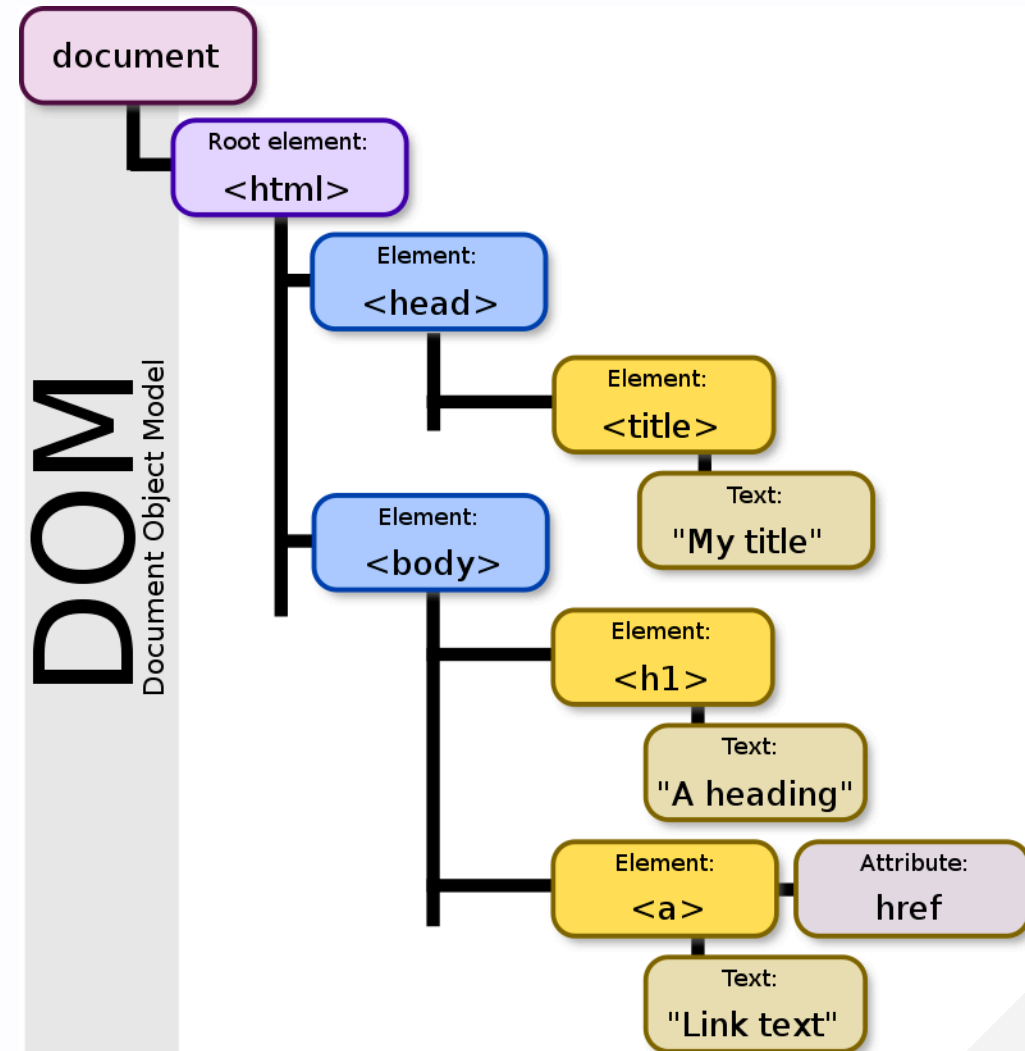

```
console.log("hello world!");
```

# Document Object Model (DOM)

HTML is just a tree, where each element is a node!

We use JavaScript to manipulate this tree.

Document Object Model

# Web Dev Basics 1

Use `document` to reference the DOM.

```
let title = document.getElementById("articleTitle");  
let loginBtn = document.getElementsByName("login")[0];  
let callouts = document.getElementsByClassName("callout"); // *
```

\*class refers to a **CSS** class

We can add *event listeners* or read/modify *properties*.

StackBlitz

Using these DOM elements, we can change the title of the article, add an action for when the button is clicked, and make all of the callouts red.

```
title.innerText = 'My Website!';
loginBtn.addEventListener("click", () => {
  alert("You are advancing to the next part of the site...");
});

for (let callout of callouts) {
  callout.style.color = "red";
}
```

## StackBlitz

# Finish ICE-WDB1

Use *today's starter code* and implement (a) the reviews button and (b) the update yield function.

# Learning Objectives

1. Manipulate the DOM via JavaScript.
2. Define a callback function.
3. Understand how asynchronous code executes.
4. Fetch, parse, and use JSON data from an API to populate webpage.

# What is JSON?

**Definition:** JavaScript Object Notation (JSON) is a structured way to represent text-based data based on JS object syntax.

# Refresher: JS Objects

**Definition:** Objects are unordered collection of related data of primitive or reference types defined using key-value pairs.

```
const instructor = {  
  firstName: "Cole",  
  lastName: "Nelson",  
  roles: ["student", "faculty"]  
}
```

# JSON Equivalent

```
{  
  "firstName": "Cole",  
  "lastName": "Nelson",  
  "roles": ["student", "faculty"]  
}
```

**What's the difference?** A JS Object is executable code; JSON is a language-agnostic representation of an object. There are also slight differences in syntax.

# You can write comments in JS Objects...

```
const drinks = [  
  {  
    name: "Mimosa",  
    ingredients: [  
      {name: "Orange Juice", hasAlcohol: false},  
      {name: "Champagne", hasAlcohol: true}  
    ]  
  },  
  {  
    name: "Vesper Martini", // shaken, not stirred  
    ingredients: [  
      {name: "Gin", hasAlcohol: true},  
      {name: "Vodka", hasAlcohol: true},  
      {name: "Dry Vermouth", hasAlcohol: true},  
    ]  
  }  
]
```

... but not in JSON!

```
[
  {
    "name": "Mimosa",
    "ingredients": [
      { "name": "Orange Juice", "hasAlcohol": false },
      { "name": "Champagne", "hasAlcohol": true }
    ]
  },
  {
    "name": "Vesper Martini",
    "ingredients": [
      { "name": "Gin", "hasAlcohol": true },
      { "name": "Vodka", "hasAlcohol": true },
      { "name": "Dry Vermouth", "hasAlcohol": true }
    ]
  }
]
```

# Conversion

Because JS Objects and JSON are so similar, it is easy to convert between them.

- `JSON.parse` JSON String → JS Object
- `JSON.stringify` JS Object → JSON string

Data fetched from an API does an implicit `JSON.parse`

# What is an API?

**Definition:** An application programming interface (API) is a set of definitions and protocols for communication through the serialization and de-serialization of objects.

JSON is a language-agnostic medium that we can serialize to and de-serialize from!

# How do we make an API request?

- Your browser!
- [cURL](#)
- [Postman](#)
- JavaScript

Try making an API request to...

- <https://v2.jokeapi.dev/joke/Any?safe-mode>
- <https://cs571api.cs.wisc.edu/rest/s25/ice/chili>

# Your Turn!

Fetch from the Jokes and CS571 APIs using...

- Your browser!
- Postman

**Note:** You can't get CS571 API data directly in your browser; you must pass a `X-CS571-ID` !

# Request for JSON

- Requests can be `synchronous` or `asynchronous` .
- `asynchronous` requests are recommended as they are *non-blocking*. Typically, they use a *callback* when the data is received and lets the browser continue its work while the request is made.

More on [synchronous/asynchronous requests](#)

# Making Asynchronous HTTP Requests

Two key methods: `XMLHttpRequest` (old) and `fetch` (new). `fetch` is a promise-based method.

- `Promise` objects represent the eventual completion/failure of an *asynchronous* operation and its resulting value.
- `async` / `await` — keywords to indicate that a function is *asynchronous* -- will learn later!

# fetch()

```
fetch(url)
  .then((response) => response.json()) // ignore the headers, get the data
  .then((data) => {                    // implicitly parses JSON to JS Object
    console.log("Data received!");
    console.log(data);
  })
  .catch(error => console.error(error)) // Print errors (if any)
```

## Fetching Jokes

# fetch()

Fetch happens *asynchronously*.

```
fetch(url)
  .then((response) => response.json())
  .then((data) => {
    console.log("I won't be printed 'til later!")
    console.log("Data takes time to fetch!")
  })
  .catch(error => console.error(error))

console.log("I will print first!")
```

StackBlitz

# fetch() from a CS571 API

```
fetch(url, {
  method: "GET",
  headers: {
    "X-CS571-ID": "bid_xxxxxxxxxxx" // generally bad practice
  }
})
.then(response => response.json())
.then(data => {
  // Do something with the data
})
.catch(error => console.error(error)) // Print errors
```

There is a database that maps your BID to a WISC ID!

# fetch() from a CS571 API

```
fetch(url, {
  method: "GET",
  headers: {
    "X-CS571-ID": CS571.getBadgerId() // better!
  }
})
.then(response => response.json())
.then(data => {
  // Do something with the data
})
.catch(error => console.error(error)) // Print errors
```

There is a database that maps your BID to a WISC ID!

# Callback Functions

`then` and `catch` take a *callback function* as an argument.

**Definition:** A *callback function* (sometimes called a *function reference*) is passed into another function as an argument, which is then invoked inside the outer function to complete a routine or action.

More on [callback functions](#)

# Callback Functions

Reminder: All of these define a function.

```
function fToC (temp) {  
  return (temp - 32) * 5/9;  
}
```

*A function definition*

```
const fToC = (temp) => {  
  return (temp - 32) * 5/9;  
}
```

*An arrow function*

```
const fToC = (temp) => (temp - 32) * 5/9
```

*With an implicit return*

# Your Turn!

Let's fetch some recipes.

<https://cs571api.cs.wisc.edu/rest/s25/ice/chili>

<https://cs571api.cs.wisc.edu/rest/s25/ice/pasta>

<https://cs571api.cs.wisc.edu/rest/s25/ice/pizza>

**Remember:** You'll need a Badger ID to access these!

# Badger IDs

You *cannot* view CS571 API data from your browser!

You need to send an `X-CS571-ID` header with each request. You can get your CS571 Badger ID with `CS571.getBadgerId()`, which grabs your Badger ID from `localStorage`, a concept we'll discuss later in the semester!

# DOM Manipulation

Earlier, we learned how to get elements from the DOM and change their text.

```
let title = document.getElementById("articleTitle");  
title.innerText = "My New Title!"
```

What if we want to *add* elements?

```
title.innerHTML = "<strong>My New Title!</strong>"
```

# DOM Manipulation

We typically prefer to *not* use `innerHTML` when adding things to the DOM. *Why?*\* Instead, we would...

```
const title = document.getElementById("articleTitle")
const newNode = document.createElement('strong')
newNode.innerText = 'My New Title!'
const newlyInsertedNode = title.appendChild(newNode);
```

\* We could still safely clear the existing text with `title.innerHTML = ''`

# Your Turn!

Let's display recipes to the page *dynamically*.

# Questions?
